

## 128-Macrocell MAX® EPLD

### Features

- 128 macrocells in eight logic array blocks (LABs)
- Eight dedicated inputs, 52 bidirectional I/O pins
- Programmable interconnect array
- Advanced 0.65-micron CMOS technology to increase performance
- Available in 68-pin HLCC, PLCC, and PGA packages

### Functional Description

The CY7C342B is an Erasable Programmable Logic Device (EPLD) in which CMOS EEPROM cells are used to configure logic functions within the device. The MAX® architecture is

100% user-configurable, allowing the device to accommodate a variety of independent logic functions.

The 128 macrocells in the CY7C342B are divided into eight LABs, 16 per LAB. There are 256 expander product terms, 32 per LAB, to be used and shared by the macrocells within each LAB.

Each LAB is interconnected with a programmable interconnect array, allowing all signals to be routed throughout the chip.

The speed and density of the CY7C342B allows it to be used in a wide range of applications, from replacement of large amounts of 7400-series TTL logic, to complex controllers and multifunction chips. With greater than 25 times the functionality of 20-pin PLDs, the CY7C342B allows the replacement of over 50 TTL devices. By replacing large amounts of logic, the CY7C342B reduces board space, part count, and increases system reliability.

Maximum Access Time	15	20	25	30	35	ns

## Pin Configurations

## Logic Array Blocks

There are eight logic array blocks in the CY7C342B. Each LAB consists of a macrocell array containing 16 macrocells, an expander product term array containing 32 expanders, and an I/O block. The LAB is fed by the programmable interconnect array and the dedicated input bus. All macrocell feedbacks go to the macrocell array, the expander array, and the programmable interconnect array. Expanders feed themselves and the macrocell array. All I/O feedbacks go to the programmable interconnect array so that they may be accessed by macrocells in other LABs as well as the macrocells in the LAB in which they are situated.

Externally, the CY7C342B provides eight dedicated inputs, one of which may be used as a system clock. There are 52 I/O pins that may be individually configured for input, output, or bidirectional data flow.

## Programmable Interconnect Array

The Programmable Interconnect Array (PIA) solves interconnect limitations by routing only the signals needed by each logic array block. The inputs to the PIA are the outputs of every macrocell within the device and the I/O pin feedback of every pin on the device.

Unlike masked or programmable gate arrays, which induce variable delay dependent on routing, the PIA has a fixed delay. This eliminates undesired skews among logic signals that may cause glitches in internal or external logic. The fixed delay, regardless of programmable interconnect array configuration, simplifies design by assuring that internal signal skews or races are avoided. The result is ease of design implementation, often in a signal pass, without the multiple internal logic

placement and routing iterations required for a programmable gate array to achieve design timing objectives.

## Timing Delays

Timing delays within the CY7C342B may be easily determined using *Warp®*, *Warp Professional™*, or *Warp Enterprise™* software by the model shown in Figure 1. The CY7C342B has fixed internal delays, allowing the user to determine the worst-case timing delays for any design.

## Design Recommendations

Operation of the devices described herein with conditions above those listed under "Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this datasheet is not implied. Exposure to absolute maximum ratings conditions for extended periods of time may affect device reliability. The CY7C342B contains circuitry to protect device pins from high static voltages or electric fields, but normal precautions should be taken to avoid application of any voltage higher than the maximum rated voltages.

For proper operation, input and output pins must be constrained to the range  $GND \leq (V_{IN} \text{ or } V_{OUT}) \leq V_{CC}$ . Unused inputs must always be tied to an appropriate logic level (either  $V_{CC}$  or  $GND$ ). Each set of  $V_{CC}$  and  $GND$  pins must be connected together directly at the device. Power supply decoupling capacitors of at least  $0.2 \mu F$  must be connected between  $V_{CC}$  and  $GND$ . For the most effective decoupling, each  $V_{CC}$  pin should be separately decoupled to  $GND$  directly at the device. Decoupling capacitors should have good frequency response, such as monolithic ceramic types have.

**Figure 1. CY7C342B Internal Timing Model**

## Design Security

The CY7C342B contains a programmable design security feature that controls the access to the data programmed into the device. If this programmable feature is used, a proprietary design implemented in the device cannot be copied or retrieved. This enables a high level of design control to be obtained since programmed data within EPROM cells is invisible. The bit that controls this function, along with all other program data, may be reset simply by erasing the entire device.

The CY7C342B is fully functionally tested and guaranteed through complete testing of each programmable EPROM bit and all internal logic elements thus ensuring 100% programming yield.

The erasable nature of these devices allows test programs to be used and erased during early stages of the production flow. The devices also contain on-board logic test circuitry to allow verification of function and AC specification once encapsulated in non-windowed packages.

## Typical $I_{CC}$ vs. $f_{MAX}$

## Output Drive Current

## Timing Considerations

Unless otherwise stated, propagation delays do not include expanders. When using expanders, add the maximum expander delay  $t_{EXP}$  to the overall delay. Similarly, there is an additional  $t_{PIA}$  delay for an input from an I/O pin when compared to a signal from straight input pin.

When calculating synchronous frequencies, use  $t_{SU}$  if all inputs are on dedicated input pins. When expander logic is used in the data path, add the appropriate maximum expander delay,  $t_{EXP}$  to  $t_{S1}$ . Determine which of  $1/(t_{WH} + t_{WL})$ ,  $1/t_{CO1}$ , or  $1/(t_{EXP} + t_{S1})$  is the lowest frequency. The lowest of these frequencies is the maximum data path frequency for the synchronous configuration.

When calculating external asynchronous frequencies, use  $t_{AS1}$  if all inputs are on the dedicated input pins.

When expander logic is used in the data path, add the appropriate maximum expander delay,  $t_{EXP}$  to  $t_{AS1}$ . Determine which of  $1/(t_{AWH} + t_{AWL})$ ,  $1/t_{ACO1}$ , or  $1/(t_{EXP} + t_{AS1})$  is the lowest frequency. The lowest of these frequencies is the maximum data path frequency for the asynchronous configuration.

The parameter  $t_{OH}$  indicates the system compatibility of this device when driving other synchronous logic with positive input hold times, which is controlled by the same synchronous clock. If  $t_{OH}$  is greater than the minimum required input hold time of the subsequent synchronous logic, then the devices are guaranteed to function properly with a common synchronous clock under worst-case environmental and supply voltage conditions.

### Maximum Ratings

(Above which the useful life may be impaired. For user guidelines, not tested.)

Storage Temperature .....  $-65^{\circ}\text{C}$  to  $+135^{\circ}\text{C}$

Ambient Temperature with Power Applied .....  $-65^{\circ}\text{C}$  to  $+135^{\circ}\text{C}$

Maximum Junction Temperature (under bias) .....  $150^{\circ}\text{C}$

Supply Voltage to Ground Potential .....  $-2.0\text{V}$  to  $+7.0\text{V}^{[1]}$

DC Output Current per Pin<sup>[1]</sup> .....  $-25\text{ mA}$  to  $+25\text{ mA}$

DC Input Voltage<sup>[1]</sup> .....  $-2.0\text{V}$  to  $+7.0\text{V}$

### Operating Range

Range	Ambient Temperature	$V_{CC}$
Commercial	$0^{\circ}\text{C}$ to $+70^{\circ}\text{C}$	$5\text{V} \pm 5\%$
Industrial	$-40^{\circ}\text{C}$ to $+85^{\circ}\text{C}$	$5\text{V} \pm 10\%$

### Electrical Characteristics Over the Operating Range

Parameter	Description	Test Conditions	Min.	Max.	Unit
$V_{CC}$	Supply Voltage	Maximum $V_{CC}$ rise time is 10 ms	4.75(4.5)	5.25(5.5)	V
$V_{OH}$	Output HIGH Voltage	$I_{OH} = -4\text{ mA DC}^{[2]}$	2.4		V
$V_{OL}$	Output LOW Voltage	$I_{OL} = 8\text{ mA DC}^{[2]}$		0.45	V
$V_{IH}$	Input HIGH Voltage		2.0	$V_{CC} + 0.3$	V
$V_{IL}$	Input LOW Voltage		-0.3	0.8	V
$I_{IX}$	Input Current	$V_I = V_{CC}$ or ground	-10	+10	$\mu\text{A}$
$I_{OZ}$	Output Leakage Current	$V_O = V_{CC}$ or ground	-40	+40	$\mu\text{A}$
$t_R$	Recommended Input Rise Time			100	ns
$t_F$	Recommended Input Fall Time			100	ns

### Capacitance

Parameter	Description	Test Conditions	Max.	Unit
$C_{IN}$	Input Capacitance	$V_{IN} = 0\text{V}$ , $f = 1.0\text{ MHz}$	10	pF
$C_{OUT}$	Output Capacitance	$V_{OUT} = 0\text{V}$ , $f = 1.0\text{ MHz}$	20	pF

### AC Test Loads and Waveforms

Equivalent to: THÉVENIN EQUIVALENT (commercial/military)

#### Notes:

1. Minimum DC input is  $-0.3\text{V}$ . During transactions, input may undershoot to  $-2.0\text{V}$  or overshoot to  $7.0\text{V}$  for input currents less than  $100\text{ mA}$  and periods shorter than  $20\text{ ns}$ .
2. The  $I_{OH}$  parameter refers to high-level TTL output current; the  $I_{OL}$  parameter refers to low-level TTL output current.

**Notes:**

3.  $C_1 = 35 \text{ pF}$ .

4. The  $f_{MAX}$  values represent the highest frequency for pipeline data.

5. This parameter is measured with a 16-bit counter programmed into each LAB.

6. This parameter is measured with a positive-edge triggered clock at the register. For negative edge triggering, the  $t_{AWH}$  and  $t_{AWL}$  parameters must be swapped.
